This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

PREFACE.

THE Metric System of Weights and Measures is used so universally in foreign books and periodicals, that much time is consumed and no little annoyance incurred by the American reader, in translating these units into their English and American equivalents, by the aid of any of the reduction tables that have yet been published. It therefore occurred to the undersigned that a handy pocket volume, for facilitating comparisons of this kind, might be acceptable to engineers and scientific workers generally. This is the *raison d'être* of the present little book. The work of calculating the tables and reading the proof has been done by Mr. A. D. Risteen, Associate Editor of THE LOCOMOTIVE, whose experience in the computing division of the United States Coast and Geodetic Survey should be a sufficient guarantee of the care and accuracy with which his task has been done. Mr. Risteen has also prepared a brief account of the inception and adoption of the Metric System in France, which adds materially to the

415726

interest and value of the volume. The Metric System is now in common use in France, Germany, Austria-Hungary, Italy, Spain, Portugal, Sweden, Norway, Belgium, The Netherlands, Roumania, Servia, Egypt, Mexico, Costa Rica, Guatemala, Nicaragua, Salvador, Brazil, Colombia, Bolivia, Chile, The Argentine Republic, Haiti, and Santo Domingo. It has also been adopted officially by Venezuela, Uruguay, Turkey, and British India, although in these four countries it can hardly yet be said to be in common use. Japan, too, has announced her intention of adopting a modified form of it, and even China has a *decimal* system of weights and measures, although it is not the French Metric System. England, Russia, and the United States are the only great nations that still refuse to adopt the Metric System. Its advantages are many, and the only really serious objection appears to be, that the change from our present units to the new ones would be more or less confusing and annoying for the first few years. Much of this annoyance and confusion could be prevented by providing school children with cheap sets of metric measures and weights, and requiring each child to measure and weigh a certain number of objects every week. In this way the units and their

names would become tolerably familiar to the next generation, and the transition would be far easier. The formidable decimals that the metric system suggests to the average citizen (and which are here very much in evidence) constitute no part of the system itself, and they could be gratefully dismissed, the moment the metric system came into use. They owe their existence to the fact that the foot, pound, and quart are not commensurable with the meter, gramme, and liter; and, when we cease to use our present units, we should also cease to use the long numbers that express their values in metric units.

J. M. ALLEN, *President.*

Hartford, Conn., May 2, 1898.

THE METRIC SYSTEM OF WEIGHTS AND MEASURES.

DIVERSITY OF SYSTEMS IN USE.

From the earliest days of civilization men have measured and weighed things, and hence they have had to have at least the rudiments of a system of weights and measures. At first, however, there was no attempt at precision in the standards used. A "foot" meant something of substantially the same length as the king's foot; and an "inch" was sometimes considered to be the twelfth part of a foot, and at other times it was defined as the space covered by three good, plump kernels of barley, placed end to end. Each community had its own units, which, in most cases, bore no relation whatever to the units employed in other communities. As wealth increased and commerce grew, it became necessary to provide for a greater degree of precision in standards, and for a comparison of those used in different localities. Undoubtedly, the innate dishonesty of man also had something to

do with the establishment of more definite standards, because in the absence of these there was nothing to prevent a person who was so inclined from buying by a long measure and selling by a short one. At all events, at the present time the units used in weighing and measuring have been defined by law in all civilized countries. This has secured, for each country, a certain degree of uniformity throughout its own territory; but among the standards of *different* countries there is a diversity almost as great as ever.

Even in the United States there are an enormous number of units in vogue. For example, for measuring lengths we have the inch, ell, nail, link, foot, yard, fathom, rod, chain, furlong, mile, knot, and doubtless many others; and the units in use for area, capacity, and weight are even more numerous. Many of these units have different values, too, according to the nature of the substance to be measured or weighed. Thus we have several kinds of ounces and pounds, and at least two kinds of quarts. There is no regularity whatever in the number of units of one kind that make one unit of the next higher kind; and some of the tables that the schoolboy has to learn are extremely distressing. We well remember what a stickler it was, in our day,

that it should take 30¼ square yards to make one square rod. If we had a simpler method of mensuration, the children in our schools could be spared a great part of this troublesome lumber, and the time saved in this way could be devoted to some far more profitable subject. Taking everything into consideration, it is certainly humiliating to reflect upon the heterogeneous "system" of weights and measures in use at the present day in a country as proud, as civilized, and as advanced (in other respects) as our own United States of America. We are not unique in this respect, it is true, for many other nations have "systems" of measurement that are fully as confusing as our own; but this is mighty cold comfort.

HISTORY OF THE METER.

To France belongs the honor of making the first systematic attempt to break through the customs of antiquity, and to substitute a new metrology for the old. Until the latter part of the eighteenth century there was the same condition of affairs in that country that prevails to-day in the United States; and in Méchain and Delambre's *Base du Système mètrique decimal* (Paris, 1806), we read of "le système incohérent de nos mesures," "l'étonnante

et scandaleuse diversité de nos mesures," etc. Several ineffectual attempts to reform the French system of weights and measures had been made, previous to 1790,* but it is from that year that the present "metric system" dates. In May, 1790, M. de Talleyrand proposed to the National Assembly of France that a new system of measures should be devised on strictly scientific principles, and that the units of length and weight in this system should be based on some natural and invariable standard. On the 8th of May the Assembly passed a resolution requesting the king, Louis XVI, to open a correspondence on the

* "Plus d'une fois on avoit présenté des projets de réferme au gouvernement, qui les avoit fait examiner : mais, malgré les rapports les plus favorables, malgré la bonne volonté des ministres, et particulièrement du contrôleur général des finances Orry, ces projets avoient toujours été repoussés ou mis en oubli. En 1788, le vœu d'une mesure uniforme fut consigné dans les cahiers de quelques balliages ; quelques savans firent entendre leur voix. Les esprits étoient alors disposés à recevoir avec enthousiasme toutes les réfermes utiles. Le système incohérent de nos mesures, outre ses inconvéniens réels, avoit un vice originel qui en fit hâter l'abolition : la confusion qui y régnoit étoit en grande partie l'ouvrage de cette féodalité que personne n'osoit plus défendre, et dont on travailloit à faire disparôitre jusqu'aux moindres vestiges. Ce concours unique de circonstances valut en accueil favorable à la proposition faite en 1790 à l'assemblée constituante par M. de Talleyrand." — Méchain et Delambre, *Base du Système mètrique decimal.*

subject with the king of England, desiring him to invite the British Parliament to co-operate with the National Assembly of France in fixing the "natural unit" which was to serve as the basis of the proposed system of weights and measures. The work was to be put in the hands of a joint commission of scientific men, half of whom were to be appointed by the French Academy of Sciences, and the other half by the Royal Society of London. In conformity with the resolution, Louis laid the matter before the English king; but "owing to the temper and the public troubles of the times, his overture met with no response. Similar applications to other nations were more successful, and in subsequent proceedings Spain, Italy, the Netherlands, Switzerland, Denmark, and Sweden, participated by sending delegates to an international commission. The system itself was, however, matured by the labors of a committee of the Academy of Sciences, embracing Borda, Lagrange, Laplace, Mongé, and Condorcet, five of the ablest mathematicians of Europe."* Lavoisier, though not a member of this committee, contributed largely to its proceedings, and the standards that were afterwards pre-

* Johnson's Cyclopædia, article *Metric System.*

pared were made under his supervision. Lavoisier, for some reason, has not received the recognition that is due him in this matter, his work being usually credited to Borda.

There were two reasons advanced for basing the new unit of length upon some absolute and invariable quantity in nature. It was said that the selection of an arbitrary unit would violate the most fundamental principle of the proposed reform; for the one distinctive feature of the new system was to be the exclusion of the last vestige of arbitrariness. This argument seems to us to be hardly worth serious consideration, for however satisfactory the unit finally chosen might be, the *selection* of that unit would necessarily be arbitrary, and hence the unit itself would be so, in some sense. The other reason advanced for the selection of a natural unit was much more logical. It was urged that a system of weights and measures based on some permanent and invariable natural quantity could be entirely reconstructed, with any desired degree of precision, even though every standard in existence were utterly destroyed.

M. de Talleyrand proposed to adopt, as the fundamental unit of length, the length of a pendulum vibrating seconds in lati-

tude 45°, "ou toute autre latitude qui pourroit être préférée" (or such other latitude as might be preferred). The committee of the Academy of Sciences considered the advisability of adopting the seconds pendulum as the unit of length, but finally rejected it, principally because it involved the conception of *time*. It seemed to them preferable to base the proposed unit on *the length of some object actually existing in nature;* and after much deliberation it was decided to adopt some one of the dimensions of the earth itself. Of the different dimensions proposed, the two that met with the most favor were the equatorial circumference, and the meridian quadrant; and of these two the meridian quadrant was finally selected, because it could be measured with greater accuracy. (The measurement of a *meridian* involves observations of *latitude*, while the measurement of the *equator* involves observations of *longitude;* and before the invention of the electric telegraph, longitude measures were subject to large errors.) In order to guard against possible differences in the lengths of the various meridian quadrants, it was decided to recommend that the new system of measures be based on the particular meridian that passes through Paris. This length (about 6,000 miles) would be

entirely out of the question as a practical unit for business purposes. However, a rough calculation showed that a standard having a length equal to one ten-millionth part of this quadrant would be convenient, and the METER (as the new unit was named)

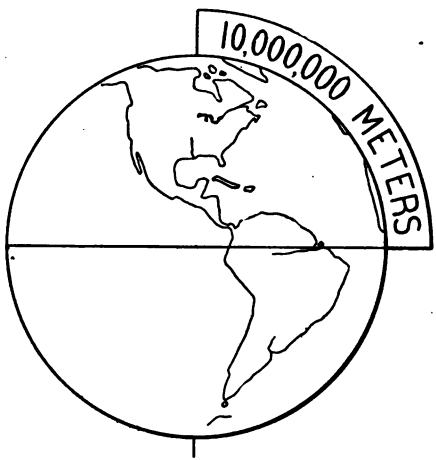

FIG. 1.— THE DEFINITION OF THE METER.

was therefore defined to be *the ten-millionth part of the distance from the equator to the north pole, measured along the sea-level, on the meridian passing through Paris.* (Fig. 1 illustrates this definition of the meter very graphically.)

The report of the committee, embodying the points explained above, and dated March 19, 1791, was approved by the Na-

FIG. 2.—SHOWING THE LINE THAT WAS MEASURED.

tional Assembly, and the work of measuring the meridian passing through Paris was begun. This operation involved immense

labor, and seven years were required to complete it. The meridian through Paris is shown by the heavy vertical line in Fig. 2. It strikes the North Sea at Dunkirk, near the Strait of Dover, in latitude 51° 02′ 8.85″, and the Mediterranean Sea at Montjouy (a small place in the suburbs of Barcelona, Spain), in latitude 41° 21′ 44.96″. The northern half of this arc was measured under the direction of Delambre, and the southern half under Méchain. A brief account of the method of measurement employed, and of the subsequent computations, will be found in the first chapter of Clarke's *Geodesy;* and the operations and calculations are described in full in Méchain and Delambre's *Base du Système mètrique décimal,* to which we have already referred. The unit of length used in measuring the meridian was the *toise,* and the final result of the seven years' work was, that the distance from the Barcelona end of the line to the Dunkirk end was 551,584.7 toises. It will be found from the data given above that the difference in latitude between the two ends was 9° 40′ 23.89″. Now the latitude of the equator is 0°, and the latitude of the pole is 90°; and therefore if the earth were a true sphere the distance from the equator to the pole would be given by the simple proportion

$9° 40' 23.89'' : 90° :: 551,584.7$ toises : distance required.

The first term of this proportion, when reduced to degrees and decimals of a degree, is $9.6733°$; and if we substitute this value of it, and then solve the proportion by the ordinary rule-of-three, we find

Distance from equator to pole = 5,131,922 toises.

In the actual calculation a small allowance had to be made for the fact that the earth is not a perfect sphere (the polar diameter being about 26 miles shorter than the equatorial diameter). It was found that to take this into account it would be necessary to subtract 1,181 toises from the distance as calculated above. Hence, it was concluded that the true distance from the equator to the pole, along the meridian of Paris, is 5,130,741 toises. One ten-millionth part of this is 0.5130741 of a toise, and this, therefore, was to be the length of the new unit, or *meter*.

The next task was to prepare a bar of platinum which should have this length. When this had been done, the length of the bar was verified by the international commission referred to above, and the commission then proceeded in a body to the Palace of the Archives, in Paris, and there they formally deposited the bar of

platinum which was to be ever afterward the standard meter of the world.

UNITS DERIVED FROM THE METER.

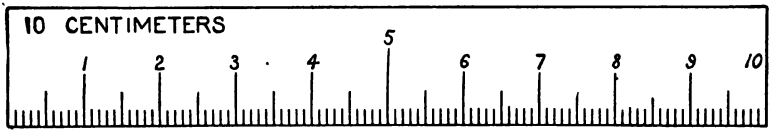
LONG MEASURE.

The meter is theoretically equal to the ten-millionth part of the meridian-quadrant that passes through Paris; but as all human measurements are liable to error, we cannot suppose that Méchain and Delambre's determination of this length is absolutely exact, and therefore for practical purposes the meter is defined to be *the length of the platinum bar that was deposited in the Palace of the Archives by the International Commission.* A comparison of this bar with the units in use in this country shows that the meter is about 3⅜ inches longer than a yard-stick. A more exact comparison, made by Professor Rogers, indicates that the precise length of the standard meter is 39.37027 inches; and a similar determination by General Comstock gave 39.36985 inches. The average of these two determinations is 39.37006 inches, which is the value adopted in this essay as the true length of the meter.

To make the new system available for general purposes, it was decided to divide the meter into ten equal parts, which were called *deci*meters. Each of these parts

was further subdivided into ten parts, called *centi*meters, and each centimeter was also divided into ten parts, called *milli*meters. (The italicised prefixes stand for "tenth," "hundredth," and "thousandth," respectively, just as the words "dime," "cent," and "mill" stand for the tenth, hundredth, and thousandth part of a dollar. We have a decimal system of coinage, and we realize its simplicity and general utility. Why not apply the same idea to our weights and measures?) Fig. 3 is a DECIMETER. The decimeter is shown subdivided into ten CENTIMETERS, and each centimeter is further subdivided into ten MILLIMETERS. Ten of these decimeters, placed end to end, would make *one meter;* and 100,000,000 of them, if laid end to end along the curved surface of the earth, would just reach from the equator to the north pole.

For measuring big distances it was proposed to establish a special unit equal to 1,000 meters. To this unit the name KILOMETER was given ("kilo" being derived from a Greek word meaning "a thousand"). The meter being equal to 39.37006 inches, it follows that the KILOMETER is equal to 39,370.06 inches — that is, to 3,280.838 feet, or 0.6213709 of a mile.



1 DECIMETER.

This scale is 1 decimeter in length, and is subdivided into 10 centimeters, and again into 100 millimeters. Since the decimeter is the tenth part of a meter, 100,000,000 of these scales, placed end to end along the meridian passing through Paris, would just reach from the equator to the north pole. A cubical box, whose inside dimensions were all equal to the length of this scale, would contain 1 liter. A kilogram of water would just fill such a box, at 39° Fahr. At this same temperature, a cube of water, 1 centimeter long, high and wide, would weigh 1 gramme.

The table for long measure, in the Metric System, is very simple. It is as follows:

10 millimeters (mm.)* = 1 centimeter.
10 centimeters (cm.) = 1 decimeter.
10 decimeters (dm.) = 1 meter.
1,000 meters (m.) = 1 kilometer (km.).

SQUARE MEASURE.

The tables for square measure and cubic measure are easily derived from this table for long measure. The area of a rectangle or square, for example, is equal to the product of the length and breadth. A square 1 decimeter (or 10 centimeters) each way will therefore have an area of 100 square centimeters: hence 1 square decimeter = 100 square centimeters. The rest of the table for square measure is constructed in the same way, and hence we have the following table:

100 square millimeters (sq. mm.) = 1 square centimeter.

100 square centimeters (sq. cm.) = 1 square decimeter.

100 square decimeters (sq. dm.) = 1 square meter.

1,000,000 square meters (sq. m.) = 1 square kilometer (sq. km.).

* The letters in parentheses indicate the customary abbreviation for the units opposite which they stand.

CUBIC MEASURE.

The table for cubic measure is constructed in the same way, by remembering that the volume of a cube is equal to the product of the length, breadth, and height. Thus a cubic meter, being 10 decimeters each way, will have the same volume as 1,000 cubic decimeters. Hence, we have the following table:

1,000 cubic millimeters (c. mm.) = 1 cubic centimeter.

1,000 cubic centimeters (c. c.) = 1 cubic decimeter.

1,000 cubic decimeters (c. dm.) = 1 cubic meter.

1,000,000,000 cubic meters (c. m.) = 1 cubic kilometer (c. km.).

The cubic meter was formerly called a *stere*, and the units derived from it were called *decisteres*, *centisteres*, etc. These names are now practically out of use, those given in the foregoing table being generally preferred.

MEASURES OF MASS.

The unit of *mass*, in the metric system, is the GRAMME. A gramme is the quantity of matter in a cubic centimeter of pure water, at the temperature of its maximum density (about 39° Fah.). It might seem more natural to take, as the unit of mass, the quan-

tity of matter in a cubic centimeter of water at the *freezing point*. There were two reasons why this was not done. In the first place, it is difficult, in experimenting with water at the exact freezing point, to make sure that the water does not contain minute needles of ice — it certainly will contain them if any part of the water under examination is exposed, even momentarily, to a temperature that is the least fraction of a degree *below* the freezing point — and the presence of such particles of ice would modify the density of the water to such an extent that it would be impossible to determine the value of the gramme with the requisite degree of precision. The second reason for preferring the temperature of maximum density in defining the gramme is, that at this point the coefficient of expansion of water is zero, so that a small change in temperature produces no sensible variation in the density of the water.

Other units of mass were derived from the gramme, in precisely the same way that other units of length were derived from the meter. Thus, the tenth part of a gramme was called a *deci*gram, the hundredth part of a gramme was called a *centi*gram, the thousandth part of a gramme was called a *milli*gram, and a weight equal to a thousand grammes was called a *kilo-*

gram. The kilogram is therefore theoretically equal to the *mass of a cubic decimeter of pure water, at its temperature of maximum density.* The weight of this quantity of water was determined experimentally by the Commission that prepared the standard platinum meter, and a standard mass of platinum, having this same weight as nearly as the unavoidable errors of experiment would allow, was deposited in the Archives of France, by the Commission, on June 22, 1799. For practical and legal purposes, therefore, *the kilogram is defined as the weight, in vacuo, of this standard mass of platinum.* Miller's comparison of this weight with the equivalents used in our own country indicates that the KILOGRAM is equal to 2.20462125 AVOIRDUPOIS POUNDS. The avoirdupois pound being equal to 7,000 troy grains, it follows that the GRAMME is equal to 15.43234875 TROY GRAINS. The table for weights in the Metric System is as follows:

10 milligrams (mgm.) = 1 centigram.
10 centigrams (cgm.) = 1 decigram.
10 decigrams (dgm.) = 1 gramme.
1,000 grammes (gm.) = 1 kilogram.
1,000 kilograms (kgm.) = 1 millier.*

It will be noticed that we have preserved the French spelling in the case of the

*Also called "tonne," or "tonneau."

gramme, although the final *me* has been dropped from the other words. This is in conformity with the recommendation of the Committee appointed by the American Association for the Advancement of Science, for considering the revision of the spelling of words used in chemistry. The *me* is dropped from the other words for the sake of simplicity, but it is preserved in the case of the *gramme* to avoid confusion with the word *grain*. The reader will see the importance of this if he will hastily write down the words *gram* and *grain*.

LIQUID MEASURE.

For measuring liquids the Commission provided a unit called a LITER, which is not greatly different from a United States liquid quart. The liter is defined as *the volume occupied by a kilogram of water at the temperature of maximum density*. For all practical purposes this is equivalent to saying that the LITER is equal to ONE CUBIC DECIMETER. A comparison with the corresponding United States measures shows that the liter is equal to 1.0563 liquid quarts, or 0.9081 dry quarts. The table for liquid measure, in the Metric System, is derived from the liter in precisely the same way as

the table for long measure is derived from the meter. Thus we have

10 milliliters (ml.) = 1 centiliter
10 centiliters (cl.) = 1 deciliter
10 deciliters (dl.) = 1 liter
1,000 liters (l.) = 1 kiloliter (kl.)

There is no distinction, in the Metric System, between "wet" and "dry" measure.

LAND MEASURE.

For convenience in measuring *land*, the unit called the ARE was proposed. The ARE is equal to the area of a square whose edges are each 10 meters long; and hence it is equivalent to 0.024711 of an acre. The table for land measure is as follows:

10 milliares (ma.) = 1 centare
10 centares (ca.) = 1 deciare
10 deciares (da.) = 1 are
10 ares (a.) = 1 decare
10 decares (dc.) = 1 hectare (hc.)

The HECTARE, equal to 2.4711 acres, is the unit commonly employed in measuring tracts of land of any considerable size.

MISCELLANEOUS UNITS.

In addition to the units of measurement that have already been mentioned, certain compound units have been tabulated in the

pages that follow. It is believed that these will be almost self-explanatory. The English and American unit for the measurement of WORK is the FOOT-POUND, which is the work that must be done to raise a pound through a height of one foot. The corresponding metric unit is the KILOGRAM-METER, which is the work that must be done in order to raise a weight of one kilogram through a height of one meter. Since a kilogram is equal to 2.20462 pounds, and a meter is equal to 3.28084 feet, it follows that one KILOGRAM-METER is equal to $2.20462 \times 3.28084 = 7.23300$ FOOT-POUNDS. The other compound units are derived in the same simple way. The only units that still call for special mention appear to be those used for the measurement of *heat* and *power*. The English unit of heat, is the quantity of heat required to raise the temperature of one pound of water one degree on the Fahrenheit scale. The corresponding metric unit is the CALORIE, which is the heat required to raise the temperature of a kilogram of water one degree on the Centigrade scale. A kilogram being equal to 2.20462 pounds, and a Centigrade degree being equal to 1.8 Fahrenheit degrees, it follows that the CALORIE is equal to $1.8 \times 2.20462 = 3.96832$ English heat units. The metric unit for meas-

uring the power of a steam engine or other prime mover is the FORCE DE CHEVAL, which is defined as equal to the performing of 4,500 kilogram-meters per minute. A kilogram-meter being equal to 7.233 foot-pounds, it follows that the FORCE DE CHEVAL is equal to $4,500 \times 7.233 = 32,549$ foot-pounds per minute. The HORSE-POWER being equal to the performance of 33,000 foot-pounds of work per minute, it follows that the FORCE DE CHEVAL is equal to $32,549 \div 33,000 = 0.98633$ of a HORSE-POWER.

THERMOMETER SCALES.

The Centigrade thermometer scale, though not properly a part of the Metric System, may be mentioned in this place. On the Fahrenheit scale the freezing point of water is defined as 32°, and the size of the degrees is fixed by defining the difference in temperature between the freezing and boiling points to be 180°. This is a clumsy sort of scale, and little can be said in favor of it except that it is in use in England and the United States. The Centigrade scale was determined by defining the freezing point of water to be 0°, and the boiling point to be 100°. The following rules result from these definitions: To convert a given reading on the Fahrenheit scale to its equivalent on the Centi-

grade scale, subtract 32° and divide the remainder by 1.8. To convert a given reading on the Centigrade scale to its equivalent on the Fahrenheit scale, multiply it by 1.8 and to the product add 32°.

USE OF THE TABLES.

The tables appended hereto are intended to facilitate the comparison of the metric system with the weights and measures used in this country. They are arranged in order, beginning with simple measures of distance, under which head centimeters are compared with inches, meters with feet, and kilometers with miles. The next set of tables refers to measures of *area*, and square inches, square feet, square yards, square miles, and acres, are compared with the corresponding metric measures. *Cubic* measure is next considered, and cubic inches, cubic feet, cubic yards, fluid ounces, dry quarts, liquid quarts, gallons, etc., are tabulated. Measures of *weight* come next, and in this set of tables we find grains, ounces, pounds, tons, etc. The last set of tables contains miscellaneous complex units, such as foot-pounds, pounds-per-square-inch, etc., which are compared with the corresponding metric units.

It is believed that these tables require

but little further explanation. If we open at any part, we find a table for reducing a given number of units in the metric system to the corresponding units employed in this country; and immediately following we find a similar table for performing the converse operation — namely, for reducing a given number of United States units to the corresponding metric equivalent. For example, if we wish to know how many square inches there are in 38 square centimeters, we turn to page 60, where we see at once that 38 square centimeters are equivalent to 5.89001 square inches. If we wish to know how many square centimeters there are in 26 square inches, we look in the immediately following table, and there we find that 26 square inches are equivalent to 167.742 square centimeters. It will be noticed that the tables run only to 100 units of any given kind. If we wish to know the value of a larger number of units than this, we may proceed as follows: If the proposed number is composed entirely of ciphers, except for the first one or two figures, we can deduce the desired equivalent directly from the tables, by merely shifting the decimal point one place to the right for every cipher that follows the significant figures

with which the proposed number begins. Thus, suppose we wished to reduce 980 cubic meters to its equivalent in cubic yards. The table that we have to use is given on pages 88 and 89. We find, here, that 98 cubic meters=128.1790 cubic yards; and hence 980 cubic meters=1281.-790 cubic yards. If we were required to reduce 4600 cubic meters to cubic yards, we should find that 46 cubic meters=60.-1657 cubic yards, and hence 4600 cubic meters=6,016.57 cubic yards. Similarly, 54,000 cubic meters=70,629.2 cubic yards, and 770,000 cubic meters=1,007,120. cubic yards. If the proposed number contains *more* than two significant figures, we may split it up into two or more other numbers, each of which consists of not more than two such figures, and then we can deduce the values of each of these partial numbers, and by adding the equivalent numbers so found, we can deduce the equivalent of the number originally proposed. Thus, suppose we wished to know how many inches there are in 4,189 centimeters. (The table that we have to use is given on pages 44 and 45.) We see that 4,189=4,100+89. Hence the operation is as follows:

4100 cm. = 1614.172 in.
89 cm. = 35.03935 in.

$\therefore$ 4189 cm. = 1649.21135 cm.

As the table does not give us the equivalent of 4100 centimeters to more than three decimal places, the value of 4189 centimeters, as obtained above, cannot be regarded as correct to more than three places of decimals. Hence we reject the last two decimals in the result already found, and we have

4189 centimeters = 1649.211 inches.

Of course we may divide up the proposed number in any way we please, for the purpose of resolving it into other numbers of two significant figures each. We wrote 4189 = 4100 + 89, merely because that is the easiest decomposition of this sort that can be found. But we might have decomposed it in any other manner. For example, we might split it up this way:

4189 = 3800 + 290 + 43 + 56.

Then the work would be:

3800 cm. =	1496.062	in.
290 cm. =	114.1732	in.
43 cm. =	16.92913	in.
56 cm. =	22.04723	in.
∴ 4189 cm. =	1649.21156	in.

Here, as before, we must regard the last two figures as inaccurate, because the table does not give us the value of 3800

centimeters to more than three places of decimals. The result obtained by splitting up a proposed number in different ways will sometimes differ among themselves by a unit in the last decimal place. This arises from the fact that only a limited number of decimal places have been preserved in the tables.

This source of apparent error can never be avoided in tabulating incommensurable quantities, for no matter how many decimal places are preserved, the last one is necessarily too great or too small, and the sum of two or more numbers taken from the table is liable to be slightly in error in the last place. If the table is accurate the error thus introduced can never exceed *one* unit in the last place when *two* tabular numbers are added; and, in general, it cannot exceed $\frac{1}{2}n$ units in the last place when n numbers are added. In the present tables, it is believed that the decimal places have been carried out far enough to ensure that errors of this sort, in practice, will have no important effect.

ERRATA.

In the references given on pages 33 to 36 inclusive, the page-numbers should all be increased by 2; so that where we *now* read "page 186," we *should* read "page 188," etc.

on pages 188 to 190 will give, at a glance, a good idea of how these two scales compare at different points; and the tables enable us to calculate, to the nearest hundredth of a degree, the reading on either one of these scales, which corresponds to a given reading on the other one. The rule for performing this calculation *without* the tables, has been given already, on page 28. It only remains to show how the calculation is facilitated by the use of the tables. The table on page 186 gives a direct comparison for every five degrees on the Centigrade scale up to 230°, and then for every ten degrees up to 470°. Suppose that a Fahrenheit thermometer and a Centigrade thermometer are exposed, side by side, to a given temperature. If the Centigrade instrument reads 170°, we see from the table that the Fahrenheit instrument will read 338°; if the Centigrade thermometer reads 0°, the Fahrenheit one will read 32°; if the Fahrenheit one reads 212°, the Centigrade one will read 100°; and if the Fahrenheit one reads 788°, the Centigrade one will read 420°. A given temperature on either scale may thus be translated directly into its equivalent on the other one, provided the given temperature can be found in the table on page 186. If it cannot be found there, we have to make use of the

auxiliary table on page 187, as illustrated in the examples which follow. Suppose the Centigrade instrument reads 42°, and we wish to know the corresponding reading on the Fahrenheit one. We do not find 42° in the Centigrade column, but we *do* find 40°, and its equivalent in the Fahrenheit system is 104°. Turning now to the auxiliary table on the next page, we see that a 2° interval on a Centigrade thermometer is equivalent to an interval of 3.6° on a Fahrenheit instrument. Hence we obtain the equivalent of 42° C., as follows:

40° C. = 104.° Fahr. (p. 186).
Correction for 2° C. = 3.6° " (p. 187).
Hence, 42° C. = 107.6° Fahr.

We might have based our calculation on any other reading in the main table, which is within 20° of the given temperature of 42° (the 20° being the greatest interval tabulated on page 187). Thus, we could base it upon the reading 55° in the first column. We note that 42° = 55° — 13°, and the calculation is as follows:

55° C. = 131.° Fahr. (p. 186).
Correction for 13° C. = 23.4° " (p. 187).
Hence, 42° C. = 107.6° Fahr.

which is the same result as we obtained before. By way of completing the expla-

nation of these tables, let us suppose that it is desired to reduce the Fahrenheit temperature 703.89° to its equivalent on the Centigrade scale. The work is as follows:

$$703.89° = 698° + 5° + .8° + .09°$$

Then

698.° Fahr. = 370.° C. (p. 186).
Correction for 5.° " = 2.78° C. (p. 187).
" " .8° " = .444°C. "
" " .09° " = .050°C. "

Hence, 703.89°Fahr. = 373.274°C.

But since the correction for 5° Fahr. is only given to two places of decimals, the *third* decimal in the result cannot have any pretension to accuracy; so that, preserving the nearest unit in the *second* decimal place, our conclusion is, that when a Fahrenheit thermometer reads 703.89°, a Centigrade thermometer, exposed to the same conditions, will read 373.27°.

INDEX TO TABLES.

Acres to hectares, 78.
Avoirdupois ounces to grammes, 130.
pounds to kilograms, 134.
British gallons to liters, 114.
heat units to calories, 162.
liquid quarts to liters, 110.
Bushels, U. S., to steres, 122.
Calories to British heat units, 160.
to foot-pounds, 164.
Centigrade.—See *Thermometer.*
Centimeters to inches, 44.
Chevaux, forces de, to horse power, 168.
Cubic centimeters to cubic inches, 80.
to U. S. fluid ounces, 96.
feet to cubic meters, 86.
inches to cubic centimeters, 82.
kilometers to cubic miles, 92.
meters to cubic feet, 84.
to cubic yards, 88.
miles to cubic kilometers, 94.
yards to cubic meters, 90.
Dry.—See *Liters, Quarts, Bushels,* and *Steres.*
English.—See *British.*
Fahrenheit.—See *Thermometer.*
Feet to meters, 50.
Fluid ounces to cubic centimeters, 98.

Foot-pounds to calories, 166.
to kilogram-meters, 158.
Forces de chevaux to horse power, 168.
Gallons, British, to liters, 114.
U. S., to liters, 106.
Grains to grammes, 126.
in a U. S. gallon to milligrams in a liter, 186.
Grammes to grains, 124.
to avoirdupois ounces, 128.
to Troy ounces, 136.
in a cubic centimeter to ounces in a cubic inch, 172.
Heat units, British, to calories, 162.
Hectares to acres, 76.
Horse power to forces de chevaux, 170.
Inches to centimeters, 46.
Kilogram-meters to foot-pounds, 156.
Kilograms to avoirdupois pounds, 132.
to Troy pounds, 140.
in a cubic meter to pounds in a cubic foot, 176.
per square centimeter to pounds per square inch, 152.
per square meter to pounds per square foot, 148.
Kilometers to miles, 56.
Liquid.—See *Quarts*, *Gallons*, and *Liters*.
Liters to British gallons, 112.
to British liquid quarts, 108.
to U. S. liquid quarts, 100.
to U. S. gallons, 104.
to U. S. dry quarts, 116.
Meters to feet, 48.
to yards, 52.
Miles to kilometers, 58.

Milliers to short tons, 144.
in a cubic meter to tons in a cubic yard, 180.
Milligrams in a liter to grains in a U. S. gallon, 184.
Ounces, avoirdupois, to grammes, 130.
U. S. fluid, to cubic centimeters, 98.
Troy, to grammes, 138.
in a cubic inch to grammes in a cubic centimeter, 174.
Pounds, avoirdupois, to kilograms, 134.
Troy, to kilograms, 142.
per square inch to kilograms per square centimeter, 154.
per square foot to kilograms per square meter, 150.
in a cubic foot to kilograms in a cubic meter, 178.
Quarts, British liquid, to liters, 110.
U. S. liquid, to liters, 102.
U. S. dry, to liters, 118.
Scales, thermometer, comparison of, 188, 189, 190.
Short tons to milliers, 146.
in a cubic yard to milliers in a cubic meter, 182.
Square centimeters to square inches, 60.
feet to square meters, 66.
inches to square centimeters, 62.
kilometers to square miles, 72.
meters to square feet, 64.
to square yards, 68.
miles to square kilometers, 74.
yards to square meters, 70.
Steres to U. S. bushels, 120.
Temperature.—See *Thermometer*.
Thermometer scales, comparison of, 188, 189, 190.
Tonnes and Tonneaux.—See *Milliers*.
